When Webinar and Meeting Follow-Ups Fall Apart

Case Study — UK B2B GTM Team

A UK-based B2B company had a strong webinar motion and strong sales motion, but they kept losing momentum after the call because the buyer's real requests were getting trapped in places that do not create follow-through.

The Reality We Built Around

This client's pipeline was driven by weekly webinars plus high-velocity demos, and that created the same messy pattern every week: buyers asked very specific questions that indicated buying intent, but internally those questions were being treated as **"notes,"** and notes do not create ownership.

The Marketing Problem

The marketing team would finish a webinar and export the Q&A as a CSV, paste it into a spreadsheet, and start answering what they could — but the questions that actually move deals forward require internal owners like security, product, PMM, or solutions, and those were the questions that died quietly because no one person felt accountable and no one tool enforced closure.

The Sales Problem

On the sales side, the AE would capture multiple buyer asks as a single free-text note in the CRM, drop three Slack pings in three different channels, then send one follow-up email that answered only one of the asks — which meant the buyer was left waiting and the vendor looked disorganised even when the product was strong.

Where It Broke — Point 1

⚠ BREAKDOWN #1

Webinar Q&A Export Became a Graveyard for High-Intent Questions

The webinar host would end the session, marketing would export Q&A, and the spreadsheet would contain raw questions like **"Do you support SCIM," "Do you have a DPA," "Can you restrict exports," "Do you integrate with Snowflake," "How do you compare to competitor Y"** — but the spreadsheet had:

No owner column

No owner column that actually meant something

No due-by time

No due-by time that triggered escalation

No CRM link

No link back to the contact record in the CRM

The most purchase-ready attendees became silent drop-offs.

Where It Broke — Point 2

⚠ BREAKDOWN #2

AEs Became Human Routers Across Five Internal Teams

In demos, AEs were being forced into the role of internal project manager because the buyer's asks were split across teams:

→ **Slack the security person**

For documents

→ **Slack the PM**

For feature confirmation

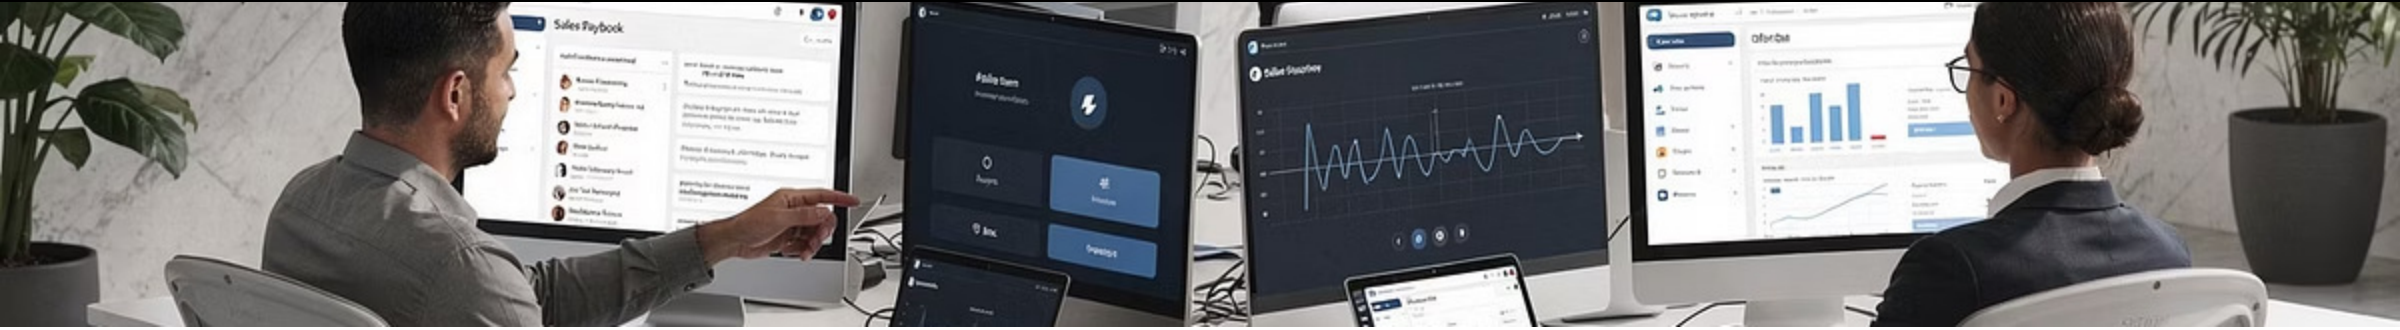
→ **Slack PMM**

For a competitor comparison sheet

→ **Slack solutions**

For integration constraints

None of those pings were connected to one shared request record, so when someone replied, it was reply-by-chat, not reply-by-closure, and the AE still had to turn those replies into an email, attach the right version of the right doc, log it in the CRM, and remember to circle back if the owner did not respond.



Where It Broke — Points 3 & 4

BREAKDOWN #3

Product Requests Arrived Without Enough Context

Feature requests were arriving as vague messages like **"prospect needs export restrictions,"** which are not answerable because the PM needs to know which roles, which export paths, which plan tier, whether the buyer wants "prevent export" or "limit export," and whether this is a deal breaker or a nice-to-have.

Because the AE is busy, the PM never gets the missing detail quickly, so the request doesn't become a Jira ticket with the correct acceptance criteria and the buyer never gets a credible response.

BREAKDOWN #4

Security and Procurement Questions Stalled

When a buyer asked for SOC2, DPA, sub-processor list, and data residency notes, the AE often sent a generic link or a stale PDF because they were pulling from memory.

Procurement came back with **"missing sub-processor list"** or **"DPA version not current,"** which forced a second round of internal chasing and made the buyer feel like the vendor was unprepared.

What We Delivered

Buyer Request Capture and Routing Module

We delivered a module that works across the two sources of truth this client already had, and pushes the output into the systems where work actually happens.

Capture Point A: Webinar Q&A

The module ingests the live Q&A feed and post-webinar questions, keeps the exact question text, the timestamp, and the attendee identity, and immediately ties it to the right CRM contact and company record so the question is not floating in a spreadsheet detached from pipeline.

Capture Point B: Call Recordings

The module uses the existing call recording system's transcript timestamps to pick out explicit buyer requests — so when a buyer says **"send me your security docs and confirm Okta SSO,"** it becomes two request items with the exact quote and the call moment link, instead of being compressed into a summary paragraph that hides what must be done next.

Where It Writes and What It Creates

CRM

Each request is written into the account and opportunity timeline as an **"Open Buyer Request"** with a category, an owner, and a due-by time, so a sales manager can see what is pending without asking the rep.

Slack or Teams

The correct owner receives a message containing the buyer's exact words, the account name and deal stage, the deadline, and the single action expected — so the owner can respond once without back-and-forth.

Jira / Ticketing

If the request is product-related, the module creates a ticket that includes the buyer's phrasing, the use case context, the deal impact flag, and the required missing fields — so PMs get something they can actually answer.

Email Draft

The module drafts the follow-up email in the AE's voice but uses approved sources and attachments, so the buyer receives a response that directly addresses the exact question instead of a generic recap.

Build posture: If a buyer request cannot be answered from an approved source, or cannot be routed to an accountable owner with a due time and a recorded outbound response, it does not get treated as "captured." It stays open, stays visible, and keeps escalating until it is closed with evidence.

How It Behaves When It Is Not Sure

When the Question Is Too Vague

If the module sees a question that is too vague to answer safely, like **"are you compliant,"** it does not pretend to answer and it does not spam the buyer with a long list of documents.

It asks one short clarification question that any buyer can answer quickly, such as **"which compliance standard are you referring to,"** and it routes the request as **"needs clarification"** with that missing field clearly shown — so internal teams do not waste time guessing and the buyer doesn't get a misleading response.

When the Owner Cannot Be Determined

If the module cannot determine the correct owner because the company has not defined ownership for that request type, it routes it to the default GTM operations owner with the category label **"owner missing."**

It forces an ownership assignment before the request can be marked closed — because the fastest way a request dies is when everyone assumes someone else owns it.

What Changed Operationally

Webinar Q&A stopped behaving like post-event admin work

Every question that mattered became an owned request tied to pipeline — no longer done "if there's time."

Sales follow-ups stopped depending on AE memory

Requests were written into the CRM as open items that stayed visible until a real response was sent and logged.

Product and security teams stopped being dragged into late-stage fire drills

They were now receiving clean packets with the exact buyer question, the account context, and the one thing needed from them — which meant they could answer faster and with less friction.

The buyer experience improved

The vendor's follow-up finally matched the buyer's question instead of sending a generic deck that forces the buyer to ask again.

What We Learned

The biggest leak

The biggest leak was not that teams forgot to follow up — it was that buyer requests were living in places that do not create closure, so even **"good teams"** looked sloppy to buyers because the handoff system was weak.

The fastest trust win

The fastest trust win was replying with the buyer's exact wording and a concrete next step, because it made the buyer feel heard and reduced repeat questioning.

The biggest time win

The biggest time win was removing the AE from the role of internal router so they could focus on the buyer instead of chasing internal teams.

Does This Sound Familiar?

Webinar Q&A exports

Do your webinar Q&A exports turn into a spreadsheet that answers only the easy questions, while the real buying questions quietly die?

AEs chasing on Slack

Do your AEs chase security, product, PMM, and solutions on Slack, and the buyer still waits because nobody owns the closure?

Vague feature requests

Do feature requests arrive internally as vague messages that cannot be answered without three more questions?

If this is real in your GTM motion, talk to us. We will plug into your webinar Q&A feed, your call recordings, your CRM, and your internal ticketing, and ship a request-routing layer that makes every buyer ask land with the right owner and stay visible until it is actually answered.
